

MASTER'S DIAGNOSTIC EXAMINATION

August 2011

Student's Name _____

INSTRUCTIONS FOR STUDENTS:

1. DO NOT put your NAME on the exam. Place the NUMBER assigned to you on the UPPER RIGHT HAND CORNER of EACH PAGE of your solutions.
2. Please start your answer to EACH QUESTION on a SEPARATE sheet of paper.
3. Use only one side of each sheet of paper.
4. You must answer all four questions: Questions I, II, III and IV.
5. Be sure to attempt all parts of the four questions. It may be possible to answer a later part of a question without having solved the earlier parts.
6. Be sure to hand in all of your exam. No additional material will be accepted once the exam has ended and you have left the exam room.
7. You may use only a calculator, pencil or pen, and blank paper for this examination. No other materials are allowed.

I attest that I spent no more than 4 hours to complete the exam. I used only the materials described above. I did not receive assistance from anyone during the taking of this exam.

Student's Signature _____

INSTRUCTIONS FOR PROCTOR:

Immediately after the student completes the exam, the student's solutions should be

faxed to 979-845-6060 or **emailed to longneck@stat.tamu.edu**

Do not send the questions, just send the student's solutions.

- (1) I certify that the time at which the student started the exam was _____
and the time at which the student completed the exam was _____
- (2) I certify that the student has followed all the **INSTRUCTIONS FOR STUDENTS** listed above.
- (3) I certify that the student's solutions were faxed to **979-845-6060** or
emailed to **longneck@stat.tamu.edu**.

Proctor's Signature _____

PROBLEM I. In a genetics experiment, investigators examined 300 chromosomes of a particular type and counted the number of sister-chromatid exchanges on each chromosome. The following table displays the number of exchanges for each of the 300 chromosomes and information about model fit.

Number of Exchanges	0	1	2	3	4	5	6	7	8	9	Total
Number of Chromosomes	5	21	40	59	62	44	42	17	7	3	300
\hat{p}_i	.018	.074	.146	.195	.196	.156	.104	.060	.030	.021	1.00
\hat{E}_i	5.4	22.2	43.8	58.5	58.8	46.8	31.2	18.0	9.0	6.3	300
O_i	5	21	40	59	62	44	42	17	7	3	300
$\frac{(O_i - \hat{E}_i)^2}{\hat{E}_i}$.030	.065	.330	.004	.174	.168	3.738	.056	.444	1.729	6.74

Summary Statistics for the number of exchanges for the 300 chromosomes were

$$N = 300$$

$$\bar{X} = 4.0$$

$$S^2 = 3.48$$

1. Using the information given above, does a Poisson model appear to be an appropriate model for the data?
 2. Estimate, using an appropriate 95% confidence interval, the average number of exchanges per chromosome.
 3. Assume that the Poisson model is the correct model. Using an $\alpha=0.05$ test, test the hypothesis that the number of exchanges per chromosome is less than 4. What is the p-value of your test?
 4. What is the power of the test developed in Question c) if the true mean number of exchanges is 3.8 per chromosome?
 5. A new study is being designed. Determine the minimum sample size which would yield an $\alpha = .05$ test of the research hypothesis that the mean number of exchanges is less than 4 with the test having power of at least 0.85 whenever the true value of the mean number of exchanges is 3.5 or smaller.
- Hint: You may assume that the sample size is large enough for the central limit theorem to be applicable.

PROBLEM II. Greens for golf courses present a unique problem for use of fertilizers in maintaining turf growth. The soil is usually very sandy and as a consequence has little capacity to retain nitrogen in the root zone after irrigation. Large initial doses of nitrogen are harmful to the grass, but slow release forms may leach out of the soil and be ineffective. A second factor that may affect nitrogen retention is the build-up of thatch, or dead grass.

A soil scientist wanted to investigate the effects of nitrogen supplied in different chemical forms and evaluate those effects combined with the effects of thatch accumulation on the quality of established turf. The first factor in his experiment is N, the form of nitrogen. He will use four forms of nitrogen, two fast release fertilizers: U = urea and AS = Ammonium Sulphate; and two slow release fertilizers: ID = Isobutylidene Diurea and SC = Sulphur Coated urea. Each fertilizer will be applied to the turf at the rate of one pound nitrogen per 1000 square feet of turf. The fertilizer will be applied each year of the experiment. The second factor is T = thatch. The thatch will be allowed to accumulate on an experimental plot for 2, 4, or 6 years. One variable of interest will be the chlorophyll content of grass clippings from the experimental plots.

The soil scientist has two choices for the experimental design:

Design A. This design would use a Randomized Complete Block Design with 12 treatment combinations (N at 4 levels and T at 3 levels). There would be two complete blocks (total of 24 observations).

Design B. This design would use a Split Plot Design with the 4 N levels as the whole plot treatments and the 3 T levels as the subplot treatments. There would be two complete blocks for the whole plot design (total of 24 observations).

1. Discuss the conditions under which each of the designs would be favored.
2. Describe the randomization procedure to be followed if the soil scientist chooses to use Design B.
3. The soil scientist uses Design B. A partial AOV table and Means table are given on the next page with notation Blocks (B), Nitrogen (N), Thatch (T). Provide the values for degree of freedom.

AOV Table

Source	DF	Mean Square
B		0.51
N		12.44
N*B		0.42
T		1.91
N*T		0.69
Error		0.21

Table of Treatment Means

		Thatch			Nitrogen Mean
		2	4	6	
Nitrogen	U	3.85	5.35	5.10	4.77
	AS	5.60	5.85	5.80	5.75
	ID	6.50	6.00	7.80	6.77
	SC	7.35	8.60	8.45	8.13
Thatch Mean		5.82	6.45	6.79	6.35

- (a) Using $\alpha=0.05$ for any tests that you may want to conduct, what is the effect of Nitrogen and Thatch on the average chlorophyll content of the grass clippings.
- (b) Are there any additional analyses you would suggest? If so, give a brief outline of these analyses. (You **do not** need to actually perform the analyses.)

PROBLEM III.

Two treatments, A and B, showed promise for treating a potentially fatal disease. A randomized experiment was conducted to determine whether there is a significant difference in the survival rate between patients who receive treatment A and those who receive treatment B. Of 154 patients who received treatment A, 38 survived for at least 15 years, whereas 16 of the 164 patients who received treatment B survived at least 15 years.

1. A double-blind experiment is one in which neither the patient nor the doctor can identify the treatment given to the patient. Treatment A can be administered only as a pill, and treatment B can be administered only as an injection. Can this randomized experiment be performed as a double-blind experiment? Why or why not?
2. Construct and interpret a 95 percent confidence interval for the difference between the proportion of the population who would survive at least 15 years if given treatment A and the proportion of the population who would survive at least 15 years if given treatment B.

In many of these types of studies, physicians are interested in the ratio of survival probabilities, $\frac{p_A}{p_B}$, where p_A represents the true 15-year survival rate for all patients who receive treatment A and p_B represents the true 15-year survival rate for all patients who receive treatment B. This ratio is usually referred to as the *relative risk* of the two treatments. For example, a relative risk of 1 indicates the survival rates for patients receiving the two treatments are equal, whereas a relative risk of 1.5 indicates that the survival rate for patients receiving treatment A is 50 percent higher than the survival rate for patients receiving treatment B. An estimator of the relative risk is the ratio of estimated probabilities, $\frac{\hat{p}_A}{\hat{p}_B}$

3. Using the data from the randomized experiment described above, compute the estimate of the relative risk.

The sampling distribution of $\frac{\hat{p}_A}{\hat{p}_B}$ is skewed. However, when both sample sizes, n_A and n_B , are relatively large, the distribution of $\log_e \left(\frac{\hat{p}_A}{\hat{p}_B} \right)$, the natural logarithm of relative risk, is approximately normal with a mean of $\log_e \left(\frac{p_A}{p_B} \right)$ and a standard deviation of $\sqrt{\frac{1-p_A}{n_A p_A} + \frac{1-p_B}{n_B p_B}}$ where p_A and p_B can be estimated by using \hat{p}_A and \hat{p}_B . When a 95 percent confidence interval for $\log_e \left(\frac{p_A}{p_B} \right)$ is known, an approximate 95 percent confidence interval for $\frac{p_A}{p_B}$, the relative risk of the two treatments, can be constructed by exponentiating the endpoints of the confidence interval for $\log_e \left(\frac{p_A}{p_B} \right)$.

4. Construct and interpret a 95 percent confidence interval for the relative risk, $\frac{p_A}{p_B}$, of the two treatments.

The *odds ratio*, $OR = \frac{p_A/(1-p_A)}{p_B/(1-p_B)} = \frac{p_A(1-p_B)}{p_B(1-p_A)}$ is another quantity that can be used to compare proportions. An estimator of the odds ratio is the sample odds ratio, $\widehat{OR} = \frac{\hat{p}_A(1-\hat{p}_B)}{\hat{p}_B(1-\hat{p}_A)}$.

5. Using the data from the randomized experiment above, compute the estimate of the odds ratio.

We will now look at a setting where we can further explore the three measures used to compare proportions. In a long-term study of British male physicians, the sample proportion who died from heart disease was 0.00140 for smokers and 0.00669 for nonsmokers.

6. Compute sample estimates of the difference in proportions, relative risk, and odds ratio of having heart disease for smokers versus nonsmokers.
7. Explain why the estimated relative risk and the estimated odds ratio have similar values.
8. Which measure(s) best indicate the relationship between the probabilities for having heart disease for smokers and nonsmokers? Explain why.

Problem IV:

Part A.

In a study of the percentage of raw material that responds in a reaction, researchers identified the following five factors:

- the feed rate of the chemicals (*FeedRate*), ranging from 10 to 15 liters per minute
- the percentage of the catalyst (*Catalyst*), ranging from 1% to 2%
- the agitation rate of the reactor (*AgitRate*), ranging from 100 to 120 revolutions per minute
- the temperature (*Temperature*), ranging from 140 to 180 degrees Celsius
- the concentration (*Concentration*), ranging from 3% to 6%

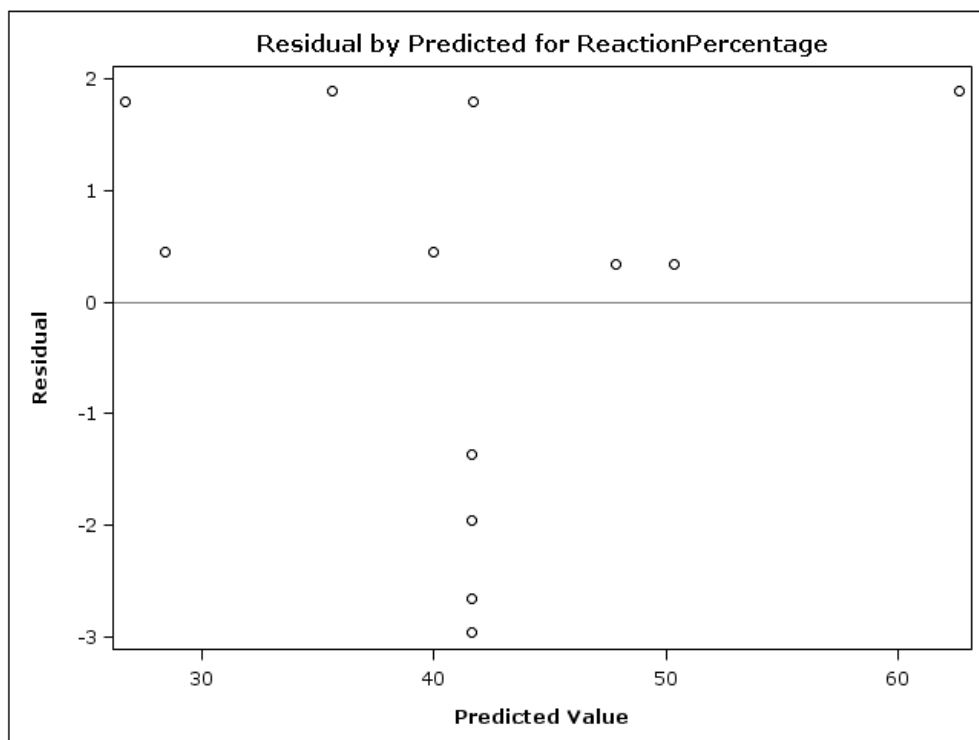

The following data set contains the results of an experiment designed to estimate main effects for all factors:

	⑫③ FeedRate	⑫③ Catalyst	⑫③ AgitRate	⑫③ Temperature	⑫③ Concentration	⑫③ ReactionPercentage
1	10	1	100	140	6	37.5
2	10	1	120	180	3	28.5
3	10	2	100	180	3	40.4
4	10	2	120	140	6	48.2
5	15	1	100	180	6	50.7
6	15	1	120	140	3	28.9
7	15	2	100	140	3	43.5
8	15	2	120	180	6	64.5
9	12.5	1.5	110	160	4.5	39
10	12.5	1.5	110	160	4.5	40.3
11	12.5	1.5	110	160	4.5	38.7
12	12.5	1.5	110	160	4.5	39.7

The model is :

$$\text{ReactionPercentage} = \beta_0 + \beta_1 * \text{FeedRate} + \beta_2 * \text{Catalyst} + \beta_3 * \text{AgitRate} + \beta_4 * \text{Temperature} + \beta_5 * \text{Concentration} + \varepsilon$$

Some of the results of the regression analyses are given below:

Analysis of Variance					
Source	DF	Sum of Squares	Mean Square	F Value	Pr > F
Model	5	990.27000	198.05400	33.29	0.0003
Error	6	35.69917	5.94986		
Corrected Total	11	1025.96917			

Root MSE	2.43923	R-Square	0.9652
Dependent Mean	41.65833	Adj R-Sq	0.9362
Coeff Var	5.85533		

Parameter Estimates						
Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > t	Variance Inflation
Intercept	1	-43.69167	13.04097	-3.35	0.0154	0
FeedRate	1	1.65000	0.34496	4.78	0.0031	1.00000
Catalyst	1	12.75000	1.72480	7.39	0.0003	1.00000
AgitRate	1	-0.02500	0.08624	-0.29	0.7817	1.00000
Temperature	1	0.16250	0.04312	3.77	0.0093	1.00000
Concentration	1	4.96667	0.57493	8.64	0.0001	1.00000

What would you recommend to your client?

Answer the above question in terms of the following questions:

1) Is this a valid model? Why or why not?

2) If you need to add interactions and squared terms, can you just add them as a group to the model and run the analyses? Why or why not?

3) What is being tested by the F value of 33.29 in the ANOVA table? Answer in terms of the β 's?

Part B.

The usual multiple linear regression model can be written as:

$$Y = X\beta + \varepsilon$$

where $V(\varepsilon) = \sigma^2 I$ and I is the $(n \times n)$ identity matrix so that $V(Y|X) = \sigma^2 I$.

However, if $V(\varepsilon) = R_{n \times n}$, then (Show work)

a) What is the $V(Y|X)$?

B) If $\hat{Y} = X\hat{\beta} = X(X'X)^{-1}X'Y = HY$ then what is $V(\hat{Y}|X)$?
